Computing with objects

Computing with even the simplest objects can be difficult and expensive.

Example: Computing with integers like $10^{500}$ is expensive (computation time, storage).

Solution: Approximate and use floating point numbers.

Problem: Approximation and original objects have different properties.

The integer $10^{500}$ has a successor ($1000...001$).

$10^{500} + 1 - 10^{500} = 1$

The floating point number $10E500$ does not have a successor!

$10E500+1-10E500=0$

1. There are workarounds

Applications

1. Example: Solving a system of equations

2. Methods offered by Gröbner bases
   In what ways can Gröbner bases help when solving equations?

3. Ideal theory
   Gröbner bases offers a complete solution to several ideal theoretic problems like ideal membership.

4. Computational aspects
   Things to think about when using Gröbner bases.
The theory tells us that the systems (1) and (2) have exactly the same set of solutions.

\begin{align*}
(1) \quad \begin{cases} 
xy + 1 = 0 \\
x^2 + x = 0
\end{cases} & \quad P = \{xy + 1, x^2 + x\} \\
\downarrow \text{Gröbner Base} \\
(2) \quad \begin{cases} 
1 + x = 0 \\
y - 1 = 0
\end{cases} & \quad G = \{1 + x, y - 1\}
\end{align*}

### Methods offered by GB

- **Solvability**
  Do a system of equations have a solution?

- **Finite/infinite number of solutions**
  Are there an infinite number of solutions (parametric solution) or not?

- **Exact number of solutions**
  Determine the exact number of solutions without solving the system.

- **Solving a system of equations**
  Two variants: Elegant and slow or hard and not-so-slow.

- **Gröbner bases compared with numerical methods**
  Are Gröbner bases the solution to every problem?
### Theory

#### Term orderings

For univariate polynomials (in one variable) there is a natural ordering of terms, but for multivariate polynomials (several variables) no such natural ordering exists.

The two most common orderings are **lexicographic** and **total degree**.

- **Lexicographic ordering** works just like when sorting words.
- **Total degree ordering** is a two-step process: Sort terms by total degree and sort terms of equal degree lexicographically.

To understand the lexicographic ordering, think of a term as a word. E.g the term $x^2y^0z^3 = x^2z^3$ should be sorted as the word $xxzzz$.

By default the **ordering of variables** are the usual one (i.e $xx$ comes before $xy$) but it is common to use a custom ordering of variables. E.g lexicographic ordering with $y > x$ will put $xy$ before $xx$.

---

**a.2.1**

---

### Theory

#### Term orderings

- **Lexiographic ordering** (called "plex" in Maple) $x > y > z$
  
  1. Write each term as a word.
  2. Define ordering of variables
  3. Sort as when sorting names

<table>
<thead>
<tr>
<th>Ex</th>
<th>xxz</th>
<th>xxyyz</th>
<th>x^3y^3</th>
</tr>
</thead>
<tbody>
<tr>

<td>$x^3y^3$</td>
<td></td>
<td>xyyyz</td>
<td>x^2y^2z</td>
</tr>
<tr>
<td>$x^3z$</td>
<td>xzzz</td>
<td>xz</td>
<td>x^2z</td>
</tr>
</tbody>
</table>

- **Total degree ordering** (called "tdeg" in Maple) $x > y > z$
  
  1. Sort by total degree
  2. Sort terms of equal degree lexicographically.

<table>
<thead>
<tr>

</tbody>
</table>
Methods offered by GB

• **Solvability**

Let \( P = \{ p_1, \ldots, p_r \} \) be an equation system written as a set of polynomials and let \( G \) be the Gröbner base of \( P \). The system is solvable if and only if \( 1 \in G \) (1 \( \in \) G implies that the equation 1 = 0 has a solution which is a contradiction).

\[
P = \{ xy^2, x - 1, y - 1 \} \quad \text{Solvability}
\]

\[
P = \{ xy^2, y - 1 \}
\]

\( G = \{ 1 \} \quad \text{Solvability}
\]

\( G = \{ x - 1, y - 1 \} \quad \text{Not solvable.}
\]

Applications

• **Finite/infinite number of solutions**

Let \( P = \{ p_1, \ldots, p_r \} \) be an equation system in variables \( x_1, \ldots, x_n \) written as a set of polynomials and let \( G \) be the Gröbner base of \( P \). Let \( H = \{ \text{hterm}(G) \} \).

Then the equation system associated with \( P \) has finitely many solutions if and only if there for all \( x_i \) is a positive integer \( m \) such that \( (x_i)^m \in H \).

\[
P = \{ xy + 1, x^2 + x \} \quad \text{Finite number of solutions.}
\]

\[
P = \{ xy, x^2 + x \}
\]

\( G = \{ 1 + x, y - 1 \} \quad \text{Finite number of solutions.}
\]

\( G = \{ x^2 + x, xy \}
\]

\( H = \{ x, y \} \quad \text{Infinite number of solutions.}
\]

\( H = \{ x^2, xy \}
\]
• Number of solutions

• Solving a system of equations, lexical ordering $x > y > z$

Lexical ordering leads to a triangularization of the system:

$$\begin{align*}
zy &= 0 \\
x + y &= 0 \\
z &= 0 \\
x + z^2 &= 0
\end{align*}$$

1. Solve for $z$ (the "smallest" variable according to $x > y > z$).
   In this example the Gröbner base does not contain a polynomial that depends only on $z$, so $z$ can take any value.
2. Solve for $y$.
   We have two equations that depend on $z$ and $y$. The second equation bounds $y$ to 0.
3. Solve for $x$.
   The first equation bounds $x$ to 0.
Methods offered by GB

• Solving a system of equations, total degree ordering

Total degree ordering does not lead to a triangularization of the system:

\[
\begin{align*}
xyz + 8z^2 &= 0 \\
x^2y - 7z &= 0 \\
2x - 2y + 1 &= 0
\end{align*}
\]

Use a special function to solve for each variable.

Applications

Now we will solve the system in Maple using Gröbner bases:

1. Calculate the Gröbner base.

\[
G1:=\text{grobner}[\text{gbasis}](\{z*x*y+8*z^2,x^2*y-7*z,2*x-2*y+1\},[x,y,z],tdeg)
\]

\[
G1:=\{-28z+4y^3-4y^2+y,2x-2y+1,16z^2+2y^2z-zy,21z^2+512z^3,3z^2+8yz^2\}
\]

2. Solve for one variable, e.g. z.

\[
\text{grobner}[\text{finduni}](z,G1);
\]

\[
21z^2+512z^3
\]

\[
\text{solve}(\text{"});
\]

\[
0,0,-21/512
\]

3. Repeat steps 4-8 for each solution w.r.t. z (only one is shown here).

4. Substitute 0 for z in G1 and use the result to calculate a new Gröbner base.

\[
G2:=\text{grobner}[\text{gbasis}](\text{eval}(G1),[x,y],tdeg);
\]

\[
G2:=[2x-2y+1,4y^3-4y^2+y];
\]
5. Solve for $x$.
\[ x^2 + 2x^3; \]
\[ > \text{solve}("; \] 0, 0, -1/2

6. Repeat the steps 7-8 for each solution w.r.t $x$ (only one is shown here).
7. Substitute 0 for $x$ in $G2$ and use the result to calculate a new Gröbner base.
\[ > x := 0; \]  
\[ x := 0; \]
\[ > G3 := \text{gbasis}(\text{eval}(G2), [y], \text{tdeg}); \]  
\[ G3 := [2y - 1]; \]
8. Solve for $y$.
\[ > \text{solve}("; \] 1/2

We now have one solution:
\[ (x, y, z) = (0, 1/2, 0) \]

Applications

Gröbner bases compared with numerical methods
### Ideal theory

With Gröbner bases, a number of problems in ideal theory are solved:

- **Ideal membership**
  Is an element a member of a given ideal?

- **Calculating with residue classes (modulo an ideal)**

- **Subideal**
  Given two ideals $I$ and $J$, are $I \subseteq J$?

- **Proper subset**
  Given two ideals $I$ and $J$, are $I \subset J$?

- **Intersection of ideals**

- **Intersection of residue classes**

### Computational aspects

- **Total degree ordering** is as fast as/faster than the "best" lexicographic ordering.

- **Often high complexity**

- **Lexicographic ordering** is very sensitive to different permutations of variables ("unstable")
# Theory

1. **Construction of objects and calculus**

2. **Integers**
   \[ Z \rightarrow Z / aZ \]

3. **Univariate polynomials**
   \[ K[X] \rightarrow K[X]/\langle p \rangle \]

4. **Multivariate polynomials**
   \[ K[X_1, \ldots, X_n] \rightarrow K[X_1, \ldots, X_n]/\langle p_1, \ldots, p_m \rangle \]

---

## Construction of objects and calculus

**Procedure:**

1. Decide for a set of objects to start from.

2. Construct an equivalence relation.

3. Set of new objects \( \leftrightarrow \) set of equivalence classes.

4. For each equivalence class, decide for one object that will represent the class (called the **class representative**).

5. Construct a function \( \text{Reduce}(.) \) that "reduces" an object to its class representative.

   - We now have a new set of objects which we can manipulate in more or less the same way as the original objects (e.g. add and multiply).

   - The new objects have properties *inherited* from the original objects. They also have some new properties that come from the equivalence relation.
Integers

**Objective:** Split integers in two parts - quotient and remainder after division by 3.

**Procedure:**
1. $\mathbb{Z}$
2. $a \sim b \iff a \mod 3 = b \mod 3$
3. New objects: $\{\ldots,-3,0,3,\ldots\}$, $\{\ldots,-2,1,4,\ldots\}$, $\{\ldots,-1,2,5,\ldots\}$
4. Representatives: 0, 1, 2
5. $Reduce(a) = a \mod 3$

**Example:**
(in $\mathbb{Z}$) $2 + 8 = 10$
(mod 3) $Reduce(2 + 8) = Reduce(10) = 1$
$Reduce(Reduce(2) + Reduce(8)) = Reduce(2 + 2) = Reduce(4) = 1$

The new objects can be treated the same way as integers, but by using the $Reduce$ function we mask away the quotient part and only consider the remainder part.

Univariate polynomials

**Objective:** Split polynomials in two parts - quotient and remainder after division by $q = x^2$.

**Procedure:**
1. $\mathbb{R}[X]$
2. $p_1 = a_1 q + r_1$ $p_2 = a_2 q + r_2$
   $p_1 \sim p_2 \iff r_1 = r_2$
3. New objects:
   $\{3x, x^2 + 3x, x^3 + x^2 + 3x, \ldots\}$,
   $\{x + 6, x^2 + x + 6, 7x^2 + x + 6, \ldots\}$,
   $\{18x, 2x^2 + 18x, 3x^3 - x^2 + 18x, \ldots\}$,
   ...
4. Representatives: $3x$, $x + 6$, $18x$
5. $Reduce(p) = p \ polmod q$

$t.2$

$t.3.1$
### Theory

#### Univariate polynomials

**Example:**

\[
\begin{align*}
(x^2 + 3x) \cdot (x + 6) &= x^3 + 9x^2 + 18x \\
\text{polmod } x^2 \text{ Reduce}((x^2 + 3x) \cdot (x + 6)) &= \text{Reduce}(3x^3 + 9x^2 + 18x) = 18x
\end{align*}
\]

The new objects can be treated the same way as ordinary polynomials, but by using the `Reduce` function we mask away the quotient part and only considers the remainder part.

### Theory

#### Multivariate polynomials

**Objective:** Split polynomials in two parts - quotient and remainder after “division” by \( q_1 = x^2y + y^2 \) and \( q_2 = xy + x^2 \). "Division" in this case means to write a polynomial as a linear combination of \( q_1 \) and \( q_2 \) and, in most cases, a remainder:

\[
p = a_1q_1 + a_2q_2 + r
\]

The new object will in this case be \( r \).

**Procedure:**

1. \( R[X, Y] \)
2. \( p_1 = a_{11}q_1 + a_{12}q_2 + r_1 \quad p_2 = a_{21}q_1 + a_{22}q_2 + r_2 \)

   \[ p_1 - p_2 \Leftrightarrow r_1 = r_2 \]

But how do we write a polynomial as a linear combination of the base polynomials?

When we had only one univariate base polynomial we could use polynomial division.

We need to generalize polynomial division to cover several and multivariate base polynomials!
Theory

Reduction

To reduce

To *reduce* one polynomial \( p \) with another polynomial \( q \) in this case means to subtract a multiple of \( q \) from \( p \):

\[ r = p - aq \]

Example:

\[ p = 2x^3y^2 + 2x^2y + 7y \quad q = x^2y + x \]

We can reduce \( p \) with \( 2xy \cdot q = 2x^3y^2 + 2x^2y \) and have

\[ r = p - 2x^2y \cdot q = 7y \]

This reduction of \( p \) to \( r \) is written as

\[ p \rightarrow r \]

and \( 7y \) is our "new object".

---

Theory

Reduction

Set of reducers

Given a polynomial \( p \) and a set of polynomials ("reducers") \( Q \), we want to know which, if any, polynomials in \( Q \) that can reduce \( p \).

This is called the "reducer set" and is calculated as

\[ R(p, Q) = \{ q \in Q \mid hterm(q) \mid hterm(p) \} \]

Example:

\[ p = xy \quad Q = \{ x, y, xy, z, x^2y \} \]

Then

\[ R(p, Q) = \{ x, y, xy \} \]
**Theory**

**Reduction**

**Reduction algorithm**

```plaintext
procedure Reduce(p, Q)

q:=0;
while p!=0 do
    while R(p, Q)!={} do
        q:=selectpoly(R(p, Q));
        a:=hmon(p)/hmon(q);
        p:=p-a*q;
    end;
    r:=r+hmon(p);
    p:=p-hmon(p);
end;
return (r);
```

---

**Example**

Let

\[ q_1 = xy + x \quad q_2 = xy + y \]

and

\[ p = xy + x + y \]

In the first iteration we have

\[ R(p, Q) = \{ q_1, q_2 \} \]

If we choose \( q_1 \) we get \( a = 1 \) and \( p = y \). We can not reduce any further so our new object is \( y \).

If we choose \( q_2 \) we get \( a = 1 \) and \( p = x \). We can not reduce any further so our new object is \( x \).

If we begin with \( p = q_1 - q_2 = x - y \) we can not reduce anything at all. But since \( p \) is a linear combination of \( q_1 \) and \( q_2 \) it should reduce to zero!
Multivariate polynomials

The last example demonstrated several weaknesses with our reduction algorithm:

- The result is not unique. Depending on how we implement selectpoly we can end up with different decompositions. Both decompositions are correct, but it would be nice if there was only one possible result (one possible "new object").

- The reduction algorithm cannot reduce every polynomial that is reducible (or should be reducible).

Is the reduction algorithm useless?

Let’s try to modify the base. We extend the base with the linear combination $q_1 - q_2$ and see what happens.

Example (continued from p t.4.2.4)

Let

\[ q_1 = xy + x \quad q_2 = xy + y \quad q_3 = x - y \]

and

\[ p = xy + x + y \]

In the first iteration we have

\[ R(p, Q) = \{ q_1, q_2, q_3 \} \]

If we choose $q_1$ we get $a = 1$ and $p = y$. We can not reduce any further so our new object is $y$.

If we choose $q_2$ we get $a = 1$ and $p = x$. We can reduce further and our new object is $x - (x - y) = y$ which is the same (new) object!

If we begin with $p = q_1 - q_2 = x - y$ we can reduce to zero in one step.
As we have seen, there are some serious problems with the reduction algorithm. We solved the problems by modifying the base.

As it turns out, the problems are not related to the algorithm, but rather to the structure of the “base” (the “base polynomials” \( q_1, q_2, \ldots \)).

With the help of another algorithm, Buchbergers algorithm, a base consisting of a number of polynomials can be transformed into a Gröbner base. Buchbergers algorithm will extend a given base with certain new elements, much in the same way as we did in the last example. Such a modified base will give us a different decomposition but the same result (same new object, same remainder).

It can be proved that the reduction algorithm will be guaranteed to always work on any Gröbner base, and since there for every polynomial base exists one unique Gröbner base that is always computable (in finite time), we can use the reduction algorithm to decompose a polynomial!

---

**Theory**

### Multivariate polynomials

As we have seen, there are some serious problems with the reduction algorithm. We solved the problems by modifying the base.

As it turns out, the problems are not related to the algorithm, but rather to the structure of the “base” (the “base polynomials” \( q_1, q_2, \ldots \)).

With the help of another algorithm, Buchbergers algorithm, a base consisting of a number of polynomials can be transformed into a Gröbner base. Buchbergers algorithm will extend a given base with certain new elements, much in the same way as we did in the last example. Such a modified base will give us a different decomposition but the same result (same new object, same remainder).

It can be proved that the reduction algorithm will be guaranteed to always work on any Gröbner base, and since there for every polynomial base exists one unique Gröbner base that is always computable (in finite time), we can use the reduction algorithm to decompose a polynomial!

---

**Theory**

### Buchbergers algorithm

**procedure** \( \text{Gbasis}(P) \)

\[
\begin{align*}
G & := P; \\
K & := \text{length}(G); \\
B & := \{[i,j]:1 \leq i < j \leq k\}; \\
\text{while} \ B \neq \emptyset \ \text{do} \\
\quad & \quad [i,j] := \text{selectpair}(B, G); \\
\quad & \quad B := B - \{i,j\}; \\
\quad & \quad h := \text{Reduce}(\text{Spoly}(G[i], G[j]), G); \\
\quad & \quad \text{if} \ h \neq 0 \text{ then} \\
\quad & \quad \quad G := G \cup \{h\}; \\
\quad & \quad \quad K := K + 1; \\
\quad & \quad \quad B := B \cup \{[i,j]:1 \leq i < k\}; \\
\quad & \quad \text{end}; \\
\text{end}; \\
\text{return}(G); 
\end{align*}
\]
3. New objects (continued from page t.4.1)
\{ 3x, 3x + x^2 y + y^2, 3x + x^3 y + xy^2, \ldots \},
\{ y + 6, y + 6 + xy^2 + x^2, 6 + y + xy^3 + x^2 y, \ldots \},
\{ 3xy + 18x, 3xy + 18x + x^2 y + y^2, \ldots \},

\ldots

4. Representatives: 3x, y + 6, 3xy + 18x

5. \textit{Reduce}(p) = \textit{Reduce}(p, Gbasis(\{q_1, q_2\}))
The Work

1. Goals with the project
2. How to execute the project
3. How to organize the material

Goals

- Texts about Gröbner Bases can roughly be divided into two categories: (1) Introductions requiring almost no mathematical background. (2) Complete texts on a graduate level.

The goal for this project was to write a textbook about Gröbner bases. It should be accessible to *anyone* with a M.Sc degree (mechanical engineering, industrial and management engineering, ...), and at the same time be mathematically correct.

- It should also teach the reader some basic "mathematical thinking". For example, in the beginning there will be a lot of explanations of what is going on.

- It should be easy to read and understand without losing mathematical precision.
Execution of the project

- Underestimated the time required for "put together".
- Good utilization of time when working in parallel.
- During the "work phase" I was often unsure about how far the total work had proceeded.
How to organize the material

Can be used in two ways:
1. Chapter order: General -> Rings -> Polynomials -> Reduction
2. Subject order: Orders/relations -> Elements -> Canonical forms

Appendix
